

Spatial Informatics Doc

1-> Load in the two layers (toposheets) into QGIS. Ignore the dialog box that pops up (click on cancel).

2-> Set the Project CRS (bottom right) to EPSG: 3741.

3) From the dialog box that appears right after setting your Project CRS, select “Inverse of Transverse Mercator + NAD27 to NAD83 (7) + NAD83 to NAD83(HARN) (47) + UTM zone 11N” for the Mariposa Layer(Appears as the first option, for me). And then, click on ‘Ok’.

4)The same dialog box appears again, now for the latter layer. Choose the transformation “Inverse of American Polyconic + NAD27 to NAD83 (7) + NAD83 to NAD83(HARN) (47) + UTM zone 11N” for it.

(Note: In Step 3 & 4, if the exact line does not appear first, look for any option that mentions NAD27 to NAD83 with an Area of use covering California / CONUS and an accuracy around 0.15m–0.2m)

5) You can now go about digitizing any overlapping (common) polygon you find from the two toposheets. Just make sure that when you create a new layer (for digitizing), the CRS you choose for it is EPSG: 3741.
